

Generally:

Create with the **T3-Stack** (<https://create.t3.gg/>) (Next.js, tRPC, Prisma with MongoDB, Zod, Tailwind, optionally NextAuth) an application that displays a list of games in a table. The data should come from a MongoDB and be made available via a tRPC endpoint.

Specifications:

- You are free to add more packages
- The focus is clearly on the backend, you can neglect the UI (or quickly solve it with a package)
- You should work on the task for a maximum of 4 hours
- You are welcome to use AI, but you should be able to explain all the code

Task:

- Create at least 1,000 mock data in a prisma seed
- The data is displayed in a table
- The data is validated
- Choose a proper way to handle the large amount of data
- Create (only in the backend) an endpoint that accepts a game data, validates it and saves it to the database
- Create an endpoint that takes releaseYear A and releaseYear B as input and returns a sum of games with an average price and the highest and lowest score per genre.

Optional:

Otherwise, you're free to add additional features within the timeframe, such as filtering, sorting, or authentication with a possible role system, or test implementation. Let your creativity run wild. What would you prioritize?

Data model (game):

- id
- title
- genre
- platform
- releaseDate
- developer
- price
- multiplayer
- metascore
